

# Maintenance of Antimicrobial Susceptibility of *Acinetobacter baumannii* in Modeled Microgravity

DONNA M HENSLEY

**OBJECTIVE:** The purpose of this study was to evaluate the effect of a modeled microgravity environment on the antimicrobial resistance of *Acinetobacter baumannii*.

**DESIGN:** Clinical isolates of *A. baumannii* (n=10) in Mueller Hinton broth were grown in high aspect ratio vessels using a rotary cell culture system oriented to achieve either normal earth gravity (1XG) or low shear modeled microgravity (LSMMG) conditions. After culture MICs were determined by Etest. Antimicrobials included in the study were amikacin, ampicillin/sulbactam, azithromycin, ceftazidime, gatifloxacin, gentamicin, imipenem, meropenem, minocycline, ticarcillin/clavulanic acid, tigecycline, and trimethoprim/sulfamethoxazole. Results were compared for MIC value and category interpretation (S, I, R).

**RESULTS:** Overall category agreement was 100% (360/360). 100% of MIC values compared were within one twofold dilution of each other.

**CONCLUSION:** Under these test conditions LSMMG had no apparent effect on the resistance pattern of *A. baumannii*.

**ABBREVIATIONS:** 1XG = normal earth gravity; LSMMG = low-shear modeled microgravity, MIC = minimum inhibitory concentration; S = susceptible; I = intermediate; R = resistant; NASA = National Aeronautics and Space Administration; RWV = rotating wall vessel; MDR = multi-drug resistant; TSA II – trypticase soy agar with 5% sheep blood; WHMC = Wilford Hall Medical Center; MHB = cation adjusted Mueller Hinton Broth; HARV = high aspect ratio vessel; RCCS = rotary cell culture system; mL = milliliter; RPM = rotations per minute.

**INDEX TERMS:** *Acinetobacter baumannii*, low-shear modeled microgravity, antimicrobial resistance

## INTRODUCTION

Growth and development of life on earth are affected by gravity.<sup>1-2</sup> The advent of space flight introduced questions regarding the effect of zero gravity, or weightlessness, on the human body. Scientists were faced with a myriad of possibilities to consider, one of which was the interaction of man and bacteria under zero or decreased gravity conditions. Although the diversity of microorganisms that have been investigated during spaceflight in the past 30 years is extensive the opportunity to conduct microbiological research in space is restricted by many factors such as demands on the astronauts' time and the difficulties of containment in an enclosed environment.<sup>3-5</sup> To meet the requirements for microbiological research in a microgravity environment NASA developed a rotating wall vessel (RWV) that created a low-shear force environment for culture of tissue cells and bacteria that mimicked the environmental conditions encountered in earth orbit. The environment created in the RWV has been termed

Low-Shear Modeled Microgravity (LSMMG) and not only mimics the space flight environment but also low-shear environments in the human body such as those found in utero and between the brush border microvilli of epithelial cells.<sup>3, 6-8</sup>

Reports in the literature have shown that bacterial phenotypic characteristics may differ in cells grown in LSMMG when compared to control cultures grown in normal earth gravity (1XG) but that the phenotypic changes in the characteristics can not be generally applied to all bacteria. For example, the growth rate of one bacterium may be increased in LSMMG while another is decreased. Other changes noted in bacteria studied are increased virulence, changes in stress response, changes in antibiotic susceptibility profiles, and increased biofilm formation.<sup>3,6,7,9-17</sup> Recently publications of molecular studies report up and down regulation of genes in bacteria grown in LSMMG when compared to 1XG cultures.<sup>3, 7, 11, 15, 18-21</sup>

*Acinetobacter baumannii* is a Gram negative bacterium commonly found in nature and in the hospital environment. It is able to survive on both moist and dry surfaces, human skin and in food. It is also characterized by a high level of antimicrobial resistance. These characteristics have lead to an increasing concern for *A. baumannii* as a potential agent for hospital acquired infections.

Reports in the literature cite an increase in *A. baumannii* infections among patients at military medical facilities treating U.S. service members who have been injured in Iraq and Afghanistan.<sup>22, 23</sup> Other studies, involving environmental and colonization cultures, indicate that the source of the *A. baumannii* infections is nosocomial in origin.<sup>24-26</sup> A study at Brook Army Medical Center, Fort Sam Houston, TX, determined the antimicrobial susceptibilities of 142 *A. baumannii-calcoaceticus* complex isolates, 95 of which were from wounded U.S. soldiers deployed overseas, and found broad antimicrobial resistance among the isolates tested. The isolates from deployed patients were more resistant than the isolates from nondeployed patients though the reason for this is unclear.<sup>27</sup> An independent association between patients with multi-drug resistant (MDR) *Acinetobacter* infection and

increased hospital and intensive care unit length of stay has been found when compared to patients with susceptible *Acinetobacter* infection.<sup>28</sup> The appearance of MDR *A. baumannii* in both military and civilian medical facilities represents a growing threat to the healthcare community.<sup>29-32</sup> Research into the growth and resistance mechanisms of this organism is needed to facilitate the development of new treatment methods.

The purpose of this study was to evaluate the effect of a low-shear force environment on the antimicrobial resistance of *Acinetobacter baumannii*. Investigation into the genomic or proteomic mechanisms of any discovered resistance pattern changes could provide new treatment targets for this emerging pathogen.

## MATERIALS AND METHODS

Clinical isolates of *A. baumannii* (n=10) were isolated from cultures submitted as standard of care to the microbiology laboratory at Wilford Hall Medical Center (WHMC), Lackland AFB, TX, and were frozen at -70° C until testing. Isolates were transferred to the WHMC Clinical Research Division microbiology laboratory for testing. Before testing each isolate was subcultured twice to trypticase soy agar with 5% sheep blood (TSA II) (BBL/BD, Sparks, MD). On test days a suspension of the *A. baumannii* isolate was prepared by harvesting cells from 16 - 24 hour growth on the TSA II plate and suspending the cells in cation adjusted Mueller Hinton Broth (MHB) (BBL/BD, Sparks, MD) and adjusting the turbidity to equal a 0.5 McFarland turbidity standard (approximately  $1.5 \times 10^8$  cells/mL). This suspension was then diluted 1:200 in MHB to achieve a working suspension of approximately  $7.5 \times 10^5$  cells/mL. 10 mL high aspect ratio vessels (HARVs) were conditioned by filling them with sterile MHB for at least 10 minutes. The conditioning MHB was discarded and the HARVs were filled with the working suspension of *A. baumannii*. Care was taken to completely fill the HARVs and to remove all air bubbles. HARVs were placed on a rotary cell culture system (RCCS) (Synthecon, Inc., Houston, TX) oriented to achieve either 1XG or LSMMG conditions (Figures 1 and 2) and incubated for 4-5 hours at 37°C, ambient air. Rotation of the HARVs was counter-clockwise at 25 RPM. After incubation the culture broth was removed from the HARVs, adjusted to 0.5

McFarland turbidity and used for MIC testing. MICs were determined by Etest (AB Biodisk North America, Piscataway, NJ). Briefly, the culture broth was applied to the surface of a Mueller Hinton Agar plate with a cotton-tipped swab. The plates were allowed to stand for 10-15 minutes and then the Etest strips were applied to the agar surface. Within 1 hour of strip application the plates were incubated for 16-24 hours at 34 - 35°C in ambient air. After incubation MICs were determined by removing the cover of the Petri dish, holding the plate to transmitted light, and reading the MIC at the point where growth intersected the Etest strip. Tests were set up in triplicate. Antimicrobials included in the study were amikacin, ampicillin/sulbactam, azithromycin, ceftazidime, gatifloxacin, gentamicin, imipenem, meropenem, minocycline, ticarcillin/clavulanic acid, tigecycline, and trimethoprim/sulfamethoxazole. Results were compared for MIC value and category interpretation of susceptible, intermediate, or resistant (S, I, R).

**Figure 1.** Rotary Cell Culture System (RCCS) in normal earth gravity (1XG) position.

## RESULTS

There was a variety of resistance patterns seen with the ten *A. baumannii* isolates. Table 1. Under these test conditions there was no difference seen in the resistance patterns of the isolates when grown under LSMMG and 1XG. Overall category agreement was 100% (360/360) and 100% of MIC values compared were within one twofold dilution of each other.

## DISCUSSION

The ever increasing impact of MDR organisms on the healthcare environment is a cause of concern for all healthcare professionals. Insight into the mechanisms of drug resistance is important if successful treatment of MDR organisms is to be achieved and there are many avenues of investigation open for study in this area. This study looked for effects on the resistance pattern of a small group of *A. baumannii* clinical isolates under a very specific set of conditions. Although no changes in resistance patterns were detected the study gives rise to a variety of other possibilities for future research.

**Figure 2.** Rotary Cell Culture System (RCCS) in low-shear modeled microgravity (LSMMG) position.

Only one speed of rotation was evaluated in this study. 25 RPM was selected because it is commonly cited in the literature as the speed of rotation used by other researchers. Some of the published work uncovered marked changes in microorganisms grown in HARVs under 1XG and LSMMG at 25 RPM. It is possible that this is not the optimal speed of rotation needed to achieve maximum low-shear force for *A. baumannii*. Other speeds of rotation could be evaluated.

The length of time the isolates were exposed to LSMMG was limited to 4-5 hours in this study. It is possible that 4-5 hours is not sufficient for the effects of incubation in LSMMG to become detectable. In an effort to determine if this was the case one isolate was incubated under LSMMG conditions for 7 days in M9 Minimal Broth before being transferred to MHB and incubated for Etest. To prevent overcrowding in the HARV over the seven day period a fresh 1:200 dilution

**Table 1.** Susceptibility patterns for individual *A. baumannii* isolates. Results are from triplicate testing at both 1XG and LSMMG.

Antimicrobial Name	ISOLATE NUMBER									
	1	2	3	4	5	6	7	8	9	10
Amikacin	S	I	I	R	S	S	S	S	S	S
Ampicillin/sulbactam	R	S	S	R	S	S	S	S	S	S
Azithromycin	R	R	R	R	R	R	R	R	R	R
Ceftazidime	R	R	I	R	R	R	S	S	S	S
Gatifloxacin	R	R	I	R	R	R	S	S	S	S
Gentamicin	R	R	R	R	S	S	S	S	S	S
Imipenem	R	R	R	R	S	S	S	S	S	S
Meropenem	R	R	R	R	S	S	S	S	S	S
Minocycline	S	S	S	R	S	S	S	S	S	S
Ticarcillin/clavulanic acid	R	R	R	R	R	R	S	S	S	S
Tigecycline	R	I	R	R	I	I	S	S	S	S
Trimethoprim/sulfamethoxazole	R	R	R	R	R	R	S	S	S	S

was made of the culture daily. The dilution was made by drawing off old culture broth and replacing it with fresh M9 broth without removing the HARV from rotation on the rotator base. The exchange was done slowly to prevent the creation of turbulence within the HARV. There was no difference in the Etest set up on the isolate after one week exposure to LSMMG when compared to the 1XG Etest. It is also possible that the 4-5 hour incubation in the HARVs was too long. Most of the culture broths removed from the HARVs after 4-5 hours had achieved turbidity greater than a 0.5 McFarland standard and had to be adjusted down to the correct turbidity before Etests could be set up. Perhaps overcrowding in the HARVs prevented the maintenance of a true LSMMG environment. Other lengths of time of exposure to LSMMG could be investigated.

One other possibility to consider is that changes did occur during incubation under LSMMG but that the changes were easily and rapidly reversed when incubated under the 1XG environment used for the Etest. It might be possible to set up an MIC in the HARVs so that the entire MIC could be performed under LSMMG conditions.

While a change in the phenotypic resistance pattern of *A. baumannii* was not detected by the test conditions utilized in this study it is possible that the optimum conditions were not achieved to create and maintain the

LSMMG environment. It is also possible that under these test conditions changes not detectable by Etest, such as proteomic, may have occurred. Further studies are needed to fully evaluate the effects of LSMMG on the resistance mechanisms of *A. baumannii*.
